Chapter 8

Application in E-Manufacturing

Chapter Objectives

This chapter aims at presenting the application of developed web quality model in e-manufacturing sector. E-manufacturing is the next big step in manufacturing development history. Web services being an integral part of e-manufacturing, it needs to be followed very carefully.

8.1 Introduction

Strictly speaking, the shop floor has always been viewed in isolation in a traditional manufacturing system. The factory operated as an autonomous unit, with its own set of goals and parameters. While this is a simple model for managing a factory, it is also inefficient and inflexible compared to manufacturing systems employing Advanced Manufacturing Technology. Leaving the production department to its own devices means it is financially unaccountable at a time when stakeholders are demanding increased returns on net assets.

While traditionally manufacturing industry was product centric in nature, the current trend is moving towards being customer centric. It has become imminently clear that making the customer the heart of the business process is essential. Relying on their products to increase profitability is no longer the answer. Customer focus is the buzzword in the manufacturing industry and the pivotal point in the business process. Manufacturers are fast accepting the fact that in order to boost sales and increase profits they need to pay more attention to customer satisfaction. Advanced Manufacturing Technology (AMT) was the next step towards being customer centric. Though Advanced Manufacturing Technology (AMT) was thought as sufficient for customer driven market approach, success was only partial in today’s internet-driven economy, that is, respond to customer demand in real-time. A real time response to the customer specific demand can only be met by integrating AMT with internet to form an integral part of e-business. This was the philosophy behind e-manufacturing. E-manufacturing encompasses different meaning to different set of people. Just like “quality” has different definitions as perceived by different set of people, the same is the case with e-manufacturing. One of the popular definitions is by AMR Research (2000):
“The core of a manufacturing strategy is the technology roadmap for information transparency between the customer, manufacturing operations, and suppliers. An e-manufacturing strategy takes e-business processes, such as build to order and reliability-centered maintenance, and generates guidelines for implementing plant systems. The e-manufacturing strategy takes the e-business and manufacturing strategies and creates a roadmap for system development and implementation in the plant.”

Another definition by Koç et al. (2003):

“E-manufacturing is a system methodology that enables the manufacturing operations to successfully integrate with the functional objectives of an enterprise through the use of Internet, tether-free (i.e., wireless, web, etc.) and predictive technologies.”

E-manufacturing, may thus, be defined as the manufacturing environment wherein all inputs (men, material, machine, money, information) are processed for transforming into customer desired output through the deployment of distributed, flexible, open, reconfigurable, scalable, extendable communication, and data management systems.

The developments in manufacturing technology have been very well depicted in figure 8.1.

![Figure 8.1 Development in manufacturing technology as adapted from Cheng and Bateman (2008)](image-url)
8.2 Enablers of e-manufacturing

Manufacturers can achieve the promise of e-Manufacturing through the enablers that drive customer oriented build-to-order processes and non-stop operations. Twelve key enablers have been identified for manufacturers to rapidly reap the benefits of e-manufacturing as discussed below.

8.2.1 Advanced Manufacturing Technology

Manufacturing has been defined by Lin and Nagalingam (2000) and Wu (1994): ‘the organized process whereby products are made or created by various production activities from raw material’.

Technology has been defined by Winner (1977) from three dimensions: apparatus, referring to the equipment itself; technique, referring to the skills and knowledge necessary to use the equipment; and organization, referring to systems and structures of control and coordination.

Advanced word only reflects the phase of manufacturing. This resulted in formation of the term ‘Advanced Manufacturing Technology’ which only reflects the current phase of manufacturing technology.

As such Advanced Manufacturing Technology can be viewed as encompassing the computer and numerical based apparatus (software and hardware) designed to accomplish or support manufacturing tasks. This definition excludes ‘managerial technologies’ but may include, for instance, information networks for shop-floor data.
8.2.2 Web enabled Technologies and Services

E-manufacturing means giving the organization agility to react quickly to changes in the market, technology and customers by operating as a virtual enterprise. To exist as a virtual enterprise web enabled technologies and services are required to integrate and synchronize information gathered based on inputs from customers, markets and technology. Web enabled decision-making portal shall perform dynamic optimization and synchronization based on the gathered information. Being one of the most important enablers of e-manufacturing it should be based on a standard yet flexible protocol to assist manufacturing platforms.

Jin et al. (2001) has discussed about web enabled technologies and services in Networked Virtual Environments (Net-VEs) which provide an insightful, intuitive and interactive system and allows effective communication among multiple users. The system allows engineers and designers to visualize, explore, manipulate and interact with manufacturing applications in Net-VEs. Additionally, the industrial users can easily apply and share the manufacturing 3D data through web. By reducing costs and cycle time of product development, such an e-manufacturing system will speed up the major activities of manufacturing engineering including simulating manufacturing processes; optimizing assembly lines and workshops design; integrating labor and equipment; and hence producing better quality products in a shorter time at more competitive price.

8.2.3 Stakeholder Interface and Feedback Mechanism

All stakeholders of a particular e-manufacturing environment should have an interface to interact with the system. The participation of stakeholders brings in the responsibility to ensure the correctness of input data and streamline the flow of information. The feedback mechanism thereby corrects any flaw in real time by equating the current process with the correct process. Particularly a Customer Relationship Management (CRM) package may be used for the purpose. In this age of the global market, with worldwide customers and remote offices, a web based software solution can help you manage your customers without any constraints of location or time.

As discussed by Lee (2001), an e-manufacturing strategy provides direct information exchanges between manufacturing and Customer Relationship Management (CRM) systems and supply chain management systems. It gives a complimentary set of
process optimization methodologies for designing, operating, maintaining or synchronizing the manufacturing operation using real time information processing through stakeholders participation.

8.2.4 Quality Tools and Techniques

The efficient and consistent operation of plant throughout the enterprise is essential to attain high productivity which has always been a focus in manufacturing. As manufacturers consolidate through acquisitions and so have new facilities to operate worldwide, they must also learn how to make products with consistent quality and efficiency at each manufacturing location. This is where initiatives like lean manufacturing drive out waste, achieving non-stop operations for maximum efficiency and output, and where techniques like Six Sigma reduce variability in processes to ensure peak quality. Such quality tools and techniques need to be infused all along the e-manufacturing system to attain error free working environment and thereby a quality product.

For achieving quality in e-manufacturing system, new standards need to be further identified and developed for the functional elements of the enabling tools for a manufacturing pant. These efforts should leverage the existing standard activities (i.e. IEEE 802.xx standard committees, MIMOSA, etc.) as discussed by Lee (2003). Rockwell Automation (2000) published a white paper stating four competencies (design, operate, maintain and synchronize) that are required for any manufacturer to be a world class manufacturing company.

8.2.5 Data Management System

Data management system basically includes mainframes which gather data from various machines and processes using internet and networking for seamless data flow. Since massive raw data is not useful unless it is reduced and transformed into information and knowledge for responsive actions, hence, data mining tools for data reduction, representation and prediction adopted for plant floor data needs to be developed. Corrective and proactive maintenance has to be implemented for the success of e-manufacturing.

As rightly depicted by Shivanand et al. (2008), the large amounts of raw data collected during a manufacturing process are rendered useless, unless the data is
gathered and transformed into some useful information which may be used to monitor a system.

8.2.6 Network Security

As the success of e-manufacturing depends on the seamless data flow across different agents of manufacturing, the security of network carrying this essential data becomes utmost critical for the working of e-manufacturing system. No compromise may be allowed on this front as any kind of interference with data may result in corrupt data being carried thereby resulting in wrong interpretation. The network has to be secured from any kind of virus or worm attack. The data which is vulnerable of being captured on internet while being transferred should be encrypted first and then transferred to the desired location.

Data/information security and vulnerability issues at the machine/product level needs to be identified and corrected as pointed by Koç et al. (2003).

8.2.7 Automation

Automation is the use of control systems and information technologies to reduce the need for human work in the production of goods and services. Automated manufacturing refers to the application of automation to produce things in the factory way. Most of the advantages of the automation technology have its influence in the manufacture processes.

The main advantage of the automated manufacturing are: higher consistency and quality, reduce the lead times, simplification of production, reduce handling, improve work flow and increase the morale of workers when a good implementation of the automation is made. Modern, information-enabled automation architecture with associated integration management services helps in eliminating human based errors.

The manufacturing enterprise is intensively deploying a host of hardware/software automation/information technologies in order to face the changing societal environment pulled by the increasing customization of both goods and services as desired by customers and discussed by Morel et al. (2007).

Pereira and Carro (2007) discusses about advances in microelectronics and software allowing embedded systems to be composed of a large set of processing elements, and the trend is towards significant enhanced functionality, complexity, and scalability, since those systems are increasingly being connected by wired and wireless networks.
to create large scale distributed real-time embedded systems (DRES). Such embedded computing and information technologies have become at the same time an enabler for future manufacturing enterprises as well as a transformer of organizations and markets.

### 8.2.8 Maintenance

By using strategies that are predictive not just preventative, maintenance is seen as an opportunity to prevent unnecessary downtime, increase plant availability and improve productivity. The efficient management of all company assets – materials, processes and employees can be a part of globally networked monitoring systems to ensure non-stop operations and optimum asset productivity. Without such a solid, efficient foundation, it is not possible to achieve the twin goals of growth and profitability simultaneously. For the purpose a web based software package may be used.

A CMMS software package maintains a computer database of information about an organization’s maintenance operations, i.e. CMMIS - computerized maintenance management information system. This information is intended to help maintenance workers do their jobs more effectively and to help management make informed decisions possibly leading to better allocation of resources. CMMS data may also be used to verify regulatory compliance.

E-Maintenance strategy should be adopted to integrate and synchronize the various maintenance and reliability applications to gather and deliver asset information where it is needed, when it is needed. Interconnectivity of the islands of maintenance and reliability information is embodied in E-Maintenance as mentioned by Shivanand et al. (2008).

### 8.2.9 Supply Chain

The supply chain tools, e-fulfillment and e-procurement solutions can be effectively implemented by direct transfer of customer order details to manufacturing personnel and equipment, configuration options and close electronic connections to suppliers and partners to optimize the inbound supply chain in the face of changing demand. The integration of manufacturing operations into the greater supply chain, both upstream and downstream will facilitate in proper synchronization. Competence in this area is best achieved after the other three are in place as discussed in Koç and Lee.
Only then is the plant truly ready to be fully coupled into an e-commerce driven supply chain.

The importance of supply chain in an e-manufacturing system may also be gauged from the definition of e-manufacturing, “E-manufacturing is the vertical (business) and horizontal (supply-chain) integration of systems to ensure the correct dissemination of information throughout the value-chain of a business, making use of appropriate technology like the internet to ensure that real-time accurate information is available at all decision points throughout an organization and supply chain.” As enumerated by Greeff and Ghoshal (2004).

Web based supply chain management (SCM) software may be integrated with e-manufacturing system for optimum productivity.

8.2.10 Interoperability of Software Systems

To achieve the goal of integrating information technology with manufacturing systems, the information must flow seamlessly from location to location without loss or corruption of data. The criticality further increases with increasing complexity of the type of data to be exchanged as more and more value-creating processes has to be inbuilt. As explained in NACFAM (2001), the ability to achieve the desired levels of
flexibility, efficiency and responsiveness to exploit the full potential of integration is yet to be realized despite the advances in information and communications technologies. The software systems used by different companies need to follow a common standard of communicating with each other in such a way to eliminate the possibility of any type of information or data loss.

8.2.11 Synchronization

Seamless integration of all tools, techniques and processes from shop floor to top floor is required to provide a basis for successful e-business. As discussed by Koç and Lee (2003) synchronization of all integral tools, techniques and processes of e-business, e-manufacturing and e-maintenance need to be addressed as shown in figure 8.3.

![Diagram of Integration of e-manufacturing with e-business and e-maintenance](image)

Figure 8.3 Integration of e-manufacturing with e-business and e-maintenance as depicted in Koç and Lee (2003).

8.2.12 Educate and Train to bring Awareness among Stakeholders

The success of e-manufacturing will ultimately depend on how well all stakeholders understand and become an integral part of it. For the purpose it is necessitated to educate and train each stakeholder for all enabling tools and techniques. They must know their participative responsibilities to optimize the performance of e-manufacturing system.
E-Manufacturing is a transformation system that enables the manufacturing operations to achieve predictive near-zero-downtime performance as well as to synchronize with the business systems through the use of web-enabled and tether-free (i.e. wireless, web, etc.) infotronics technologies. It integrates information and decision making among data flow (of machine/process level), information flow (of factory and supply system level), and cash flow (of business system level) as discussed in Koç and Lee (2003).

8.3 Role of Web Quality in E-manufacturing

The enablers of e-manufacturing discussed above focus on the fact that the web should be an inherent part of the manufacturing system and all stakeholders of the organization must adopt it. Manufacturing organization need to evaluate and streamline the existing processes with customers, suppliers, distributors and others to optimize their effectiveness in e-manufacturing system.

Since web system is an integral part of an e-manufacturing system, it facilitates achievement of intended objectives. Figure 8.1 shows a macroscopic view of a typical e-manufacturing system.

As visible from the figure 8.1, integration of diverse nature of inputs, has been identified as the most significant problem facing the industry as it attempts to realize data-driven decision-making in high-volume manufacturing. It is imperative that integration be completed with high volume of data carriers along with a standard web quality system, so that factories can focus on optimizing their manufacturing process and not data integration.

Factories are preparing for an increased volume of data, but if factory information and control systems are not poised to convert this information into actionable decisions to redirect equipment and factory operations, the systems will produce no tangible benefits. Recent moves toward computer and Web-based standards are very encouraging. This trend must accelerate to facilitate manufacturing industry and to take advantage of the equipment and factory control software using latest web technologies.

The developed system will allow dispersed engineering team members to work together productively, as if they were under one roof. The platform will meet the requirements for quicker, easier, secure and cost-effective collaborations for manufacturing.
Figure 8.4 Macroscopic View of an E-manufacturing System
The entire factory can thus, truly be optimized using intelligent factory schedulers, which in turn, must have access to equipment and data of their status as well as information on spare parts, labor, materials and chemicals, customer orders, finished inventories, in-line maintenance, and final test. To achieve this level of optimization, quality software is required. The increased availability of these data will enable predictive and preventive maintenance. A continuous real-time supply of information about the status of the factory, its equipment, process status, new orders, inventories of finished product, and spare parts must be used to continuously optimize factory operations in real time. Standardized interfaces for underlying sub systems and equipment that generate data need to be developed to merge these diverse data sets. Researchers are investigating and solving the security and confidentiality issues associated with the proposed manufacturing framework. The work includes trust mechanisms among distributed partners and solutions for confidentiality protection for virtual manufacturing networks. The work also relates to digital rights management for accessing and sharing information.

The role of web enabled software, already a critical component of every factory, is becoming even more crucial to achieving productivity improvements. Software reliability affects the time required to install and qualify new equipment. The software needed to acquire, analyze, and deliver actionable decisions must be robust and production-worthy. Unambiguous requirements, detailed usage scenarios and exception-handling guidance for high-volume manufacturing, and software testing strategies are all necessary to produce software of sufficient quality to meet these challenges. Both equipment software and third-party software need to be tested based on developed web quality model before installation.

8.4 Concluding Remarks

Existing foundations of the company should be used to build upon for incremental successes along the way. An e-manufacturing strategy will help the organization embrace information transparency, fostering operational excellence while cutting down on wastes.

While implementation of e-manufacturing requires attention towards each critical factor, specific enabler requires more attention towards specific critical factor. For Advanced Manufacturing Technology the factors need to taken care of include Adaptability, Architecture, Code Reusability, Collaboration, Communication, Fault
Tolerance, Stability, and User Friendliness. *Web enabled technologies and services* refer to attention towards all critical factors as mentioned in Figure 4.6.

*Stakeholder interface and feedback mechanism* seek more attention towards Availability, Clarity, Communication, Completeness, Multi Language Support, and User Friendliness. Implementation of *Quality tools and techniques* require more attention towards Assurance, Clarity, Communication, Completeness, Comprehensibility, Maturity, Multi Language Support, Responsiveness, Security, Stability, Suitability, Support, Trustworthy, and Understandability.

Organizations are now trying to create a wonderful experience for their customers and are focusing more on the experience that their customer has which stems from a deep desire on the customer’s part to have a good relationship with the company. This will ensure a better managed e-manufacturing system within e-business.
