List of Tables

3.1 The calculated preformation probability $P_0$ and penetrability $P$ using PCM, for various clusters with $^{208}$Pb as the daughter product, for cases of spherical, $\beta_2$ alone, and ($\beta_2, \beta_3$ and $\beta_4$) deformed nuclei, and “optimum” orientations. ................................................. 54

3.2 Half-life times and other characteristic quantities for cluster decays of various parent nuclei. The calculations are made for use of the Preformed Cluster Model (PCM) of Gupta and collaborators [17–19, 79], for cases of spherical, $\beta_2$ alone and ($\beta_2, \beta_3$ and $\beta_4$) deformed nuclei, and “optimum” orientations of cold decay process [48]. The impinging frequency $\nu_0 \sim 10^{21}$ s$^{-1}$, fixed for each case. $Q_{MN}$ refers to Q-value calculated by using the binding energies of Möller et al. [52]. .............................................................. 58

3.3 The cluster-decay half-lives for some best preformed clusters in the neighborhood of $^{34}$Si from $^{238}$U, calculated on Preformed Cluster Model (PCM) of Gupta et al. [17–19, 79] by using the Q-values ($Q_{MN}$) based on binding energies from Möller et al. [52]. The experimental data is known only for $^{34}$Si decay of $^{238}$U [92].......................... 61

4.1 Calculated fusion-evaporation cross-sections $\sigma_{Cal}^{Cal}$ due to LPs, compared with the experimental $\sigma_{Exp}$ data of Ref. [95]. Also tabulated are the calculated IMF cross-sections $\sigma_{IMF}^{Cal}$ and HMF cross-sections $\sigma_{HMF}^{Cal}$ due to light-mass and heavy-mass windows, the symmetric-fission component $\sigma_{SF}^{Cal}$, and their sum, the fusion-fission cross-section $\sigma_{ff}^{Cal}$, compared with the CASCADE data of Ref. [95], $\sigma_{ff}^{CASCADE}$. The zeros in the last column are as quoted in [95]. In DCM calculations, Light, Heavy, and SF windows refer, respectively, to $A_2=5-20$ and 40-50 and (A/2)$\pm20$. The neck-length parameter $\Delta R$ used for LP’s and fusion-fission (=IMFs+HMFs+SF) are different as are determined in Fig. 4.9 by fitting the experimental $\sigma_{Exp}$ in Fig. 4.8 and CASCADE $\sigma_{ff}^{CASCADE}$ in Fig. 4.11................................. 74
4.2 Calculated fusion-evaporation cross-sections $\sigma_{\text{cal.}}^{\text{expt}}$ due to LPs, compared with the experimental $\sigma_{\text{expt.}}^{\text{expt.}}$ data of Ref. [104]. The neck-length parameter $\Delta R$ used for LPs is determined in Fig. 4.17 by fitting the experimental $\sigma_{\text{cal.}}^{\text{expt.}}$ in Fig. 4.16. Also heavy fragments are predicted at four higher energies in the form of three windows namely: IMFs cross-sections $\sigma_{\text{IMF}}^{\text{IMF}}(A_2=5-16)$, HMFs cross-sections $\sigma_{\text{HMF}}^{\text{HMF}}(A_2=33-41)$ and the symmetric-fission component $\sigma_{\text{SF}}^{\text{SF}}$, $((A/2)\pm7)$ and their sum $\sigma_{\text{f}}^{\text{f}}$ fusion-fission cross-section. Clear formation of theses windows is shown in Fig. 4.18.

5.1 Calculated fusion-evaporation cross-sections $\sigma_{\text{cal.}}^{\text{expt.}}$ of LPs ($1 \leq Z \leq 2$, A=2-4 for $^{114,116}$Ba* and 5 for $^{118,120,122}$Ba*), compared with the experimental $\sigma_{\text{expt.}}^{\text{expt.}}$ $\sigma_{\text{cal.}}^{\text{expt.}}$ ($6 \leq Z \leq 28$) data of Ref. [101]. Also listed are the calculated IMFs cross-sections $\sigma_{\text{IMF}}^{\text{IMF}}(Z=3-5)$, which is not observed experimentally. $\sigma_{\text{IMF}}^{\text{IMF}}$ and HMFs cross-sections $\sigma_{\text{HMF}}^{\text{HMF}}$ due to light-mass and heavy-mass fragments, the near symmetric-fission component $\sigma_{\text{SF}}^{\text{SF}}$, the symmetric-fission component $\sigma_{\text{SF}}^{\text{SF}}$, and their sum, the fusion-fission cross-section $\sigma_{\text{ff}}^{\text{ff}}$ ($=\sigma_{\text{IMF}}^{\text{IMF}}+\sigma_{\text{HMF}}^{\text{HMF}}+\sigma_{\text{SF}}^{\text{SF}}+\sigma_{\text{SF}}^{\text{SF}}$), compared with the experimental fusion-fission cross-section $\sigma_{\text{ff}}^{\text{ff}}$ ($6 \leq Z \leq 28$) data of Ref. [100], also the total cross-section calculated on DCM $\sigma_{\text{cal.1}}^{\text{expt.}}$ ($=\sigma_{\text{expt.}}^{\text{expt.}}+\sigma_{\text{ff}}^{\text{ff}}$) is compared with total experimental cross-section $\sigma_{\text{total}}^{\text{expt.}}$ ($=\sigma_{\text{expt.}}^{\text{expt.}}+\sigma_{\text{f}}^{\text{f}}$ ($Z=6-28$)). In DCM calculations, IMFs, HMFs, nSF and SF windows are described separately for different CN in the literature. The neck-length parameter $\Delta R$ used for different regions are different as are determined in Fig. 5.3 by fitting the experimental $\sigma_{\text{expt.}}^{\text{expt.}}$.
