SUMMARY & CONCLUSION
To summarize, this study which was conducted in Maharani Laxmi Bai Medical College, Jhansi to compare the effect of drugs Aspirin versus clopidogrel in secondary prevention of stroke was a randomized single blinded study, included 54 patients of acute ischemic stroke and followed for one year, found out that:

➤ Both Aspirin and clopidogrel are effective in reducing the overall incidence of combined risk of ischemic stroke, myocardial infarction, or vascular death recurrent ischemic events in patients of ischemic stroke.

➤ When compared with each other, effect of clopidogrel is statistically similar to aspirin in secondary prevention of ischemic stroke.

➤ In terms of safety profile Clopidogrel is at least as safe as regular strength aspirin.

➤ The higher cost of clopidogrel is a disadvantage over aspirin so when patient is allergic to aspirin or aspirin is causing side effects clopidogrel is a good and equally effective option to aspirin in these patients.
