Lectures on Colour and Monochromic Photography by Sir Henry Dixon, F.R.S.

The color of things visible, in natural light, is due to the fact that the eye is a colorimeter, and that the eye sees colors by means of the spectrum. The eye is a colorimeter because it contains a series of colors, each of which is capable of exciting a sensation of light. The sensation of light is produced by the action of the eye on the retina, which is a layer of tissues at the back of the eye. The retina contains a number of different types of cells, each of which is sensitive to a different part of the spectrum. The sensation of color is produced by the action of a combination of these cells on the retina. The sensation of color is produced by the action of a combination of these cells on the retina. The sensation of color is produced by the action of a combination of these cells on the retina.
