CONCLUSION
CONCLUSIONS

1. Allergic patients usually have a familial background.

2. As Bronchial asthma has an multivariate etiology and in present study also most cases of Bronchial asthma were sensitive to more than one allergen so the procedure of desensitization is cumbersome and its therapeutic efficacy is doubtful.

3. There is relation of Eosinophilia with intestinal parasitemia but intestinal parasitemia is not related with skin prik test reactivity.

4. Eosinophilia is predominately, associated with allergic disorders.
