SUMMARY

This study is designed to find out whether there is any relationship between parental behaviour and the personality of their child. The whole personality is not the focus of this study. Only the introversion-extroversion dimension of personality has been given coverage here. This investigation comprises (i) assessment of the child's personality, (ii) assessment of parents' behaviour. The personality of the child was assessed by a Personality Inventory constructed by the present investigator and parental behaviour was assessed by the adapted version of Roe-Siegelman PCR Questionnaires. The findings of this investigation is based on a sample of 100. Significant relationship has been found between mothers' behaviour and the child's personality, but the amount of this relationship is very low. No such significant relationship has been found between the child's personality and his father's behaviour. The present researcher's conclusion is that mother's behaviour has definite impact on the personality of the child, whereas the father has no such influence on the child, so far the present sample is concerned.
