- From the present study it can be seen that application of an extra four hours of light in an aquaculture farm reduces feed cost and increases growth of the fishes.

- Given the present scenario of increased cost of electricity, farmers can also explore the option of solar energy to provide energy for the lighting.

- Further this being a preliminary study, cost efficiency of this method has to be evaluated. Besides the protocol applied in the present study, application of different photoperiod in combination with different feeding regimes should be taken up to come up with more effective results.

- Application of similar protocol at different life stages can be done to study at which stage of the life cycle this treatment is more effective.
