the maturity of the oocytes or fertilization or reproductive outcome in the positive patients.

DNA integrity is a more objective marker of sperm function. It is therefore conceivable that DNA integrity assessment studies have a pivotal diagnostic and prognostic role in infertile men opting for assisted reproductive techniques (ART). Further studies are needed to determine AMH and INHIBIN value to predict clinical pregnancy in IVF outcome. The relationship of AMH and INHIBIN B and the quality of oocytes have to be confirmed with larger population to get better outcome of ART.
