Phase-Diffusion Pattern in Quantum-Nondemolition Systems
Phase-diffusion pattern in quantum-nondemolition systems

We quantitatively analyze the dynamics of the quantum phase distribution associated with the reduced density matrix of a system, as the system evolves under the influence of its environment with an energy-preserving quantum nondemolition (QND) type of coupling. We take the system to be either an oscillator (harmonic or anharmonic) or a two-level atom (or equivalently, a spin-1/2 system), and model the environment as a bath of harmonic oscillators, initially in a general squeezed thermal state. The impact of the different environmental parameters is explicitly brought out as the system starts out in various initial states. The results are applicable to a variety of physical systems now studied experimentally with QND measurements.

I. INTRODUCTION

The theory of open quantum systems addresses the problems of damping and dephasing in quantum systems by its assertion that all real systems of interest are in fact “open” systems, each surrounded by its environment. Quantum optics provided one of the first testing grounds for the application of the formalism of open quantum systems [1]. The application of open system ideas to other areas of physics was intensified by the works of Caldeira and Leggett [2], and Zurek [3] among others. Most such studies are based on a model describing quantum Brownian motion of a simple harmonic oscillator in a harmonic oscillator environment. In such a model studied by Caldeira and Leggett [2], the coordinate of the particle was coupled linearly to the harmonic oscillator reservoir, and it was also assumed that the system and the environment were initially separable. The treatment of the quantum Brownian motion has since been generalized to the physically reasonable initial condition of a mixed state of the system and its environment by Bakim and Ambegaokar [4], Smith and Caldeira [5], Grabert, Schramm, and Ingold [6], and by us for the case of a system in a Stern-Gerlach potential [7], and also for quantum Brownian motion with nonlinear system-environment couplings [8].

The recent upsurge of interest in the problem of open quantum systems is because of the spectacular progress in manipulation of quantum states of matter (atoms, or bosonic or fermionic gases or molecules), encoding, transmission, and processing of quantum information, for all of which understanding and control of the environmental impact are essential. For such open quantum systems, there exists an important class of energy-preserving measurements in which dephasing occurs without damping of the system. This may be achieved with a particular type of coupling between the system and its environment, viz., when the Hamiltonian \( H_{SR} \) of the system commutes with the Hamiltonian \( H_S \) describing the system-reservoir interaction, i.e., \( H_{SR} \) is a constant of motion generated by \( H_S \) [9–11]. This condition describes a particular type of quantum-nondemolition (QND) measurement scheme.

In general, a class of observables that may be measured repeatedly with arbitrary precision, with the influence of the measurement apparatus on the system being confined strictly to the conjugate observables, is called QND or back-action evasive observables [12,13]. Such a measurement scheme was originally introduced in the context of the detection of gravitational waves [14–20]. The experimental progress on QND measurements has since been summarized in a review by Bocko and Onofrio [21]. The dynamics of decoherence in continuous atom-optical QND measurements has been studied by Onofrio and Viola [22]. In addition to its relevance in ultrasensitive measurements, a QND scheme provides a way to prepare quantum mechanical states which may otherwise be difficult to create, such as Fock states with a specific number of particles. It has been shown that the accuracy of atomic interferometry can be improved by using QND measurements of the atomic populations at the inputs to the interferometer [23]. QND systems have also been proposed for engineering quantum dynamical evolution of a system with the help of a quantum meter [24]. We have recently studied such QND open system Hamiltonians for two different models of the environment describable as baths of either oscillators or spins, and found an interesting connection between the energy-preserving QND Hamiltonians and the phase space area-preserving canonical transformations [25].

As stated above, in the context of energy-preserving QND systems, the only effect of the environment on the system is dephasing and it is a natural question to ask about the pattern of diffusion of “phases” in such a situation. Such a question is particularly relevant in the context of a number of practical phase measurement schemes [23,26].

What is the precise meaning of the quantum mechanical phase? The quantum description of phases [27] has a long history [28–32]. Pegg and Barnett [31], following Dirac [28], carried out a polar decomposition of the annihilation operator and defined a Hermitian phase operator in a finite-dimensional Hilbert space. In their scheme, the expectation
value of a function of the phase operator is first carried out in a finite-dimensional Hilbert space, and then the dimension is taken to the limit of infinity. However, it is not possible to interpret this expectation value as that of a function of a Hermitian phase operator in an infinite-dimensional Hilbert space [33,34]. To circumvent this problem, the concept of phase distribution for the quantum phase has been introduced [33,35]. In this scheme, one associates a phase distribution to a given state such that the average of a function of the phase operator in the state, computed with the phase distribution, reproduces the results of Pegg and Barnett.

In this paper we address the problem of quantum phase diffusion and study the dynamics of the quantum phase distribution associated with the reduced density matrix of the system for a number of situations of practical importance, as the system evolves under the influence of its environment with an energy-preserving QND coupling. One may take the system to be either an oscillator (harmonic or anharmonic) or a two-level atom (or equivalently, a spin-1/2 system). The phase distributions associated with the quantum state for the two cases are defined. The environment is modeled as a bath of harmonic oscillators, and the impact of the environmental parameters is quantified for different initial states of the system.

The plan of the paper is as follows. In Sec. II, we briefly discuss a generic energy-preserving QND system in the context of open systems [36]. The bath is taken to be initially in a squeezed thermal state, from which the common thermal bath results may be easily extracted by setting the squeezing parameters to zero. In Sec. III, we define the phase distribution for an oscillator system, following Agarwal et al. [35]. In Sec. III A in particular, we consider a harmonic oscillator system in QND interaction with its environment [26]. We study two different initial conditions of the system starting (1) in a coherent state and (2) in a squeezed coherent state. In Sec. III B, we study the case where the system is an anharmonic oscillator, which could arise, for example, from the interaction of a single mode of the quantized electromagnetic field with a Kerr medium [37,38]. The Hamiltonian in this case can be expressed in terms of the generators of the group SU(1,1). Using the positive discrete series representation of this group, we construct its phase distribution and study it for two different situations: (1) when the system is initially in a Kerr state, and (2) when it is initially in a squeezed Kerr state [37]. In Sec. IV we consider the phase distribution for a two-level atom, extensively used as a model system in quantum computation [39–41]. Following the phase distribution of angular momentum systems introduced by Agarwal and Singh [42], we construct and study the phase distribution of the system for three different initial conditions of the system, starting (1) in a Wigner-Dicke state [43], which is the atomic analogue of the standard Fock state [44], (2) in an atomic coherent state, which is the atomic analogue of the Glauber coherent state [44], and (3) in an atomic squeezed state [42,45]. In Sec. V we present our conclusions.

II. GENERIC QND OPEN SYSTEMS

We consider the following Hamiltonian describing the interaction of a system with its environment, modeled as a reservoir of harmonic oscillators, via a QND type of coupling [36]:

\[ H = H_S + H_R + H_{SR} = H_S + \sum_k \hbar \omega_k b_k^\dagger b_k + H_S \sum_k g_k (b_k + b_k^\dagger) + H_S^2 \sum_k \frac{g_k^2}{\hbar \omega_k}. \]  

(1)

Here \( H_S \), \( H_R \), and \( H_{SR} \) stand for the Hamiltonians of the system, reservoir, and system-reservoir interaction, respectively. \( H_S \) is a generic system Hamiltonian which we will specify in the subsequent sections to model different physical situations. \( b_k^\dagger, b_k \) denote the creation and annihilation operators for the reservoir oscillator of frequency \( \omega_k \); \( g_k \) stands for the coupling constant (assumed real) for the interaction of the oscillator field with the system. The last term on the right-hand side of Eq. (1) is a renormalization inducing "counter term." Since \( [H_S, H_{SR}] = 0 \), the Hamiltonian (1) is of QND type. The system plus reservoir composite is closed, obeying a unitary evolution given by

\[ \rho(t) = e^{-iH_{th}t} \rho(0) e^{iH_{th}t}, \]  

where

\[ \rho(0) = \rho^s(0) \rho_R(0), \]  

i.e., we assume separable initial conditions. The reservoir is assumed to be initially in a squeezed thermal state, i.e., it is a squeezed thermal bath, with an initial density matrix \( \rho_R(0) \) given by

\[ \rho_R(0) = S(r, \Phi) \rho_{th} S^\dagger(r, \Phi), \]  

where

\[ \rho_{th} = \prod_k \left[ 1 - \sigma^{\Phi} \omega_k \right] e^{-\beta \hbar \omega_k b_k^\dagger b_k}, \]  

(5)

is the density matrix of the thermal bath, and

\[ S(r_k, \Phi_k) = \exp \left[ \frac{b_k^2}{2} e^{-2i\Phi_k} - \frac{b_k^{12}}{2} e^{2i\Phi_k} \right], \]  

(6)

is the squeezing operator with \( r_k, \Phi_k \) being the squeezing parameters [46]. We are interested in the reduced dynamics of the "open" system of interest \( S \), which is obtained by tracing over the bath degrees of freedom. Using Eqs. (1) and (3) in Eq. (2) and tracing over the bath variables, we obtain the reduced density matrix for \( S \), in the system eigenbasis, as [36]

\[ \rho_{nm}^S(t) = e^{-i(E_n - E_m)\hbar t} e^{-i(E_n^2 - E_{nm}^2) \sum_k \frac{g_k^2}{\hbar^2 \omega_k^2} \sinh(\omega_k t)} \times \exp \left[ -\frac{1}{2} (E_m - E_n) \sum_k \frac{g_k^2}{\hbar^2 \omega_k^2} \coth \left( \frac{\beta \hbar \omega_k}{2} \right) \right] \times \left[ (e^{i \omega_k t} - 1) \cosh(r_k) + (e^{-i \omega_k t} - 1) \right] \times \sinh(r_k) e^{2i\Phi_k} \rho_{nm}(0). \]  

From Eq. (7) we obtain the master equation as
PHASE-DIFFUSION PATTERN IN QUANTUM-

\[ \dot{\rho}_{nm}(t) = \left[ -\frac{i}{\hbar} (E_n - E_m) + i \eta(t)(E_n^2 - E_m^2) \right. \\
\left. - (E_n - E_m)^2 \gamma(t) \right] \rho_{nm}(t), \]

where

\[ \eta(t) = -\sum_k \frac{g_k^2}{\hbar^2 \omega_k^2} \sin(\omega_k t), \]

and

\[ \gamma(t) = \frac{1}{2} \sum_k \frac{g_k^2}{\hbar^2 \omega_k^2} \cosh \left( \frac{\beta \hbar \omega_k}{2} \right) \left( e^{i\omega_k t} - 1 \right) \cosh(r_k) \]
\[ + (e^{-i\omega_k t} - 1) \sinh(r_k) e^{2\Phi_k} \]

For the case of an ohmic bath with spectral density

\[ I(\omega) = \frac{\gamma_0}{\pi} \omega e^{-\omega/\omega_c}, \]

where \( \gamma_0 \) and \( \omega_c \) are bath parameters, \( \eta(t) \) and \( \gamma(t) \) can be evaluated \cite{36}, and we quote the results as follows:

\[ \eta(t) = -\frac{\gamma_0}{\pi} \tan^{-1}(\omega_c t), \]

and

\[ \gamma(t) = \frac{\gamma_0}{2\pi} \cosh(2r) \ln(1 + \omega_c^2 t^2) \]
\[ - \frac{\gamma_0}{4\pi} \sinh(2r) \ln \left[ \frac{1 + 4\omega_c^2 (t-a)^2}{1 + \omega_c^2 (t-2a)^2} \right] \]
\[ - \frac{\gamma_0}{4\pi} \sinh(2r) \ln(1 + 4a^2 \omega_c^2), \]

at \( T=0 \), with \( t > 2a \).

As discussed in the Introduction, it is more convenient to deal with the quantum phase distribution than a Hermitian quantum phase operator. Following Agarwal et al.\cite{35} we define a phase distribution \( \mathcal{P}(\theta) \) for a given density operator \( \rho \) as

\[ \mathcal{P}(\theta) = \frac{1}{2\pi} \int_0^{2\pi} \rho_{nm} e^{i(n-m)\theta} d\theta, \]

where the states \( |\theta\rangle \) are the eigenstates of the Susskind-Glogower\cite{29} phase operator corresponding to eigenvalues of unit magnitude and are defined in terms of the number states \( |n\rangle \) as

\[ |\theta\rangle = \sum_{n=0}^{\infty} e^{i\theta |n\rangle}. \]

The sum in Eq. (16) is assumed to converge. The phase distribution is positive definite and normalized to unity.

A. System of a harmonic oscillator

For the case where the system \( S \) is a harmonic oscillator with the Hamiltonian

\[ H_S = \hbar \omega \left( a^\dagger a + \frac{1}{2} \right), \]

the number states serve as an appropriate basis for the system Hamiltonian and the system energy eigenvalue in this basis is

\[ E_n = \hbar \omega \left( n + \frac{1}{2} \right). \]

Using this in Eq. (7) we obtain

\[ \rho_{nm}^{(t)}(\omega) = e^{-i\omega(n-m)} e^{i((\omega_0^2)(n-m)(\omega_0^2)(n+m+1))} \eta(n-m) e^{-(\hbar \omega^2)(n-m)(\omega_0^2)(n+m+1)} \rho_{nm}^{(0)}, \]

where \( \eta(t) \) and \( \gamma(t) \) are as in Eqs. (9) and (10), respectively.

The Hamiltonian described here has been used by Turchette et al.\cite{26} to describe an experimental study of the decoherence and decay of quantum states of a trapped atomic ion’s harmonic motion interacting with an engineered high-temperature “phase reservoir,” which is simulated by random variations in the trap frequency—changing the phase of the ion oscillation without changing its energy, i.e., adiabatically modulating the trap frequency. In such a system it would be interesting to construct the quantum phase distribution associated with the reduced density matrix of the system and obtain the dynamics of the phase distribution as the system evolves under the influence of its environment. Equation (20) when substituted in Eq. (16) provides us with the phase distribution of the harmonic oscillator system interacting with its environment via a QND type of interaction.
Now we obtain the phase distributions for some physically interesting initial conditions of our harmonic oscillator system $S$.

1. System initially in a coherent state

The initial density matrix of the system is

$$\rho'(0) = |\alpha\rangle\langle\alpha|,$$  \hspace{1cm} (21)

where

$$\alpha = |\alpha|e^{i\theta_0}$$  \hspace{1cm} (22)

is a coherent state [47]. Thus the initial density matrix in the system basis is

$$\rho'_{\alpha,m}(0) = \langle m | \alpha \rangle \langle \alpha | m \rangle.$$  \hspace{1cm} (23)

Now making use of the expansion of the coherent state in terms of the number states we get

$$\langle m | \alpha \rangle = |\alpha|^m e^{-|\alpha|^2/2} (m! / \sqrt{m!}).$$  \hspace{1cm} (24)

It is to be noted that each of the diagonal elements of the above density matrix (23) is given by a Poisson distribution. Using Eq. (24) (and its complex conjugate) in Eq. (23), substituting it in Eq. (20), and then using Eq. (20) in Eq. (16) we obtain the phase distribution as

$$P(\theta) = \frac{1}{2\pi\sin(\omega t)} \sum_{m,n=0}^\infty \frac{|\alpha|^m e^{-|\alpha|^2/2} e^{-i\omega(m-n)(\alpha-\alpha^*)} e^{-i\omega(n-m)\theta} |\alpha|^n e^{-|\alpha|^2/2} e^{-i\omega(n-m)(\alpha-\alpha^*)}}{m! \cdot n! \cdot \sqrt{m!} \cdot \sqrt{n!}} \times e^{i(h\omega)^2(n-m)(n+me+1)/2t} e^{i(h\omega)^2(m-n)^2/2t}.$$  \hspace{1cm} (25)

Figure 1 depicts the behavior of the quantum phase distribution $P(\theta)$ given by Eq. (25), as a function of $\theta$ (in radians) as it evolves under different environmental conditions. It can be clearly seen that in comparison with the unitary evolution (continuous curve), as the temperature $T$ increases, the phase distribution broadens thereby indicating increasing phase diffusion with $T$. The phase diffusion also increases with an increase in the value of the squeezing parameter $r$, defined by Eq. (15), as is evident from a comparison of the large-dashed and the dot-dashed curves. Also by comparing the dot-dashed and double dot-dashed curves indicating the same environmental conditions but different evolution times, it can be seen that an increase in exposure time to the environment causes a corresponding increase in phase diffusion. The broadening of the curves in all cases takes place in such a fashion that the normalization of the phase distribution function is preserved. For all the figures in this paper, we have set $\omega=1.0$, $\omega_s=100$, $|\alpha|^2=5$, $a=0.0$, and $\theta_0$ [Eq. (22)] = 0.

2. System initially in a squeezed coherent state

The initial density matrix of the system is

$$\rho'(0) = |\xi, \alpha\rangle \langle \xi, \alpha|,$$  \hspace{1cm} (26)

where the squeezed coherent state is defined as [47]

$$|\xi, \alpha\rangle = S(\xi) D(\alpha) |0\rangle.$$  \hspace{1cm} (27)

Here $S$ denotes the standard squeezing operator and $D$ denotes the standard displacement operator [47]. The initial density matrix (26) in the system basis is

\begin{figure}
\centering
\includegraphics[width=\textwidth]{fig1.png}
\caption{Quantum phase distribution $P(\theta)$ given by Eq. (25), for a harmonic oscillator initially in a coherent state, as a function of $\theta$ (in radians), for different environmental conditions and evolution times. The parameters have been taken as $\omega=1.0$, $\omega_s=100$, $|\alpha|^2=5$, $a=0.0$, $\gamma_0=0.0025$. The small-dashed and the large-dashed curves are for temperatures $T$ (in units with $\hbar=1$) = 0 and 300, respectively, with an environmental squeezing parameter $r=2$ and at an evolution time $t=0.1$. The dot-dashed and the double dot-dashed curves are at evolution times $t=0.1$ and 0.2, respectively, for $T=300$ and $r=1$. The continuous curve represents unitary evolution ($\gamma_0=0$).}
\end{figure}

\begin{figure}
\centering
\includegraphics[width=\textwidth]{fig2.png}
\caption{Quantum phase distribution $P(\theta)$ given by Eq. (29), for a harmonic oscillator initially in a squeezed coherent state, as a function of $\theta$ (in radians), for different environmental conditions and evolution times. The parameters have been taken as $\omega=1.0$, $|\alpha|^2=5$, $a=0.0$, $\gamma_0=0.0025$; $r_1=0.5$, and $\psi=\pi/4$ [$r_1$ and $\psi$ are the system squeezing parameters (26)]. The small-dashed and the large-dashed curves are for temperatures $T$ (in units with $\hbar=1$) = 0 and 300, respectively, at an environmental squeezing parameter (15) $r=2$ and evolution time $t=0.1$. The dot-dashed and the double dot-dashed curves are at evolution times $t=0.1$ and 0.2, respectively, with $T=300$ and $r=1$. The continuous curve represents unitary evolution ($\gamma_0=0$).}
\end{figure}
\[
\rho_{n,m}^n(0) = \langle m | \rho^n(0) | n \rangle = \frac{e^{i(\phi_{m-n}/2)}}{2^{(m+n)/2} \sqrt{m! n!}} \frac{[\tanh(r_1)]^{(m+n)/2}}{\cosh(r_1)} \exp[-|\alpha|^2[1 - \tanh(r_1)\cos(2\theta_0 - \psi)]] \times H_m^* \left( \frac{[|\alpha|e^{i(\phi_0 - \psi)/2}]}{\sinh(2r_1)} \right) H_n \left( \frac{[|\alpha|e^{i(\phi_0 - \psi)/2}]}{\sinh(2r_1)} \right),
\]

where \( \xi = r_1 e^{i\phi} \). Here \( H_m[z] \) is a Hermite polynomial. Using Eq. (28) in Eq. (20) and substituting it in Eq. (16) we obtain the phase distribution as

\[
D(\vartheta) = \frac{1}{2\pi} \sum_{m,n=0} e^{i(\phi_{m-n}/2)} \frac{[\tanh(r_1)]^{(m+n)/2}}{\cosh(r_1)} \times \exp[-|\alpha|^2[1 - \tanh(r_1)\cos(2\theta_0 - \psi)]] \times H_m \left( \frac{[|\alpha|e^{i(\phi_0 - \psi)/2}]}{\sinh(2r_1)} \right) H_n^* \left( \frac{[|\alpha|e^{i(\phi_0 - \psi)/2}]}{\sinh(2r_1)} \right) e^{-i\omega(\omega^2(m-n)(m+n+1))\vartheta(t)} e^{-(\omega^2(m-m)^2)\vartheta(t)}. \tag{29}
\]

Figure 2 clearly indicates an increase in phase diffusion, corresponding to a broadening of the phase distribution curve, with an increase in \( T \) or bath squeezing parameter \( \gamma \) or evolution time \( t \), as was the case in Fig. 1. An interesting difference can be seen in the phase distribution curves corresponding to unitary evolution (continuous curves) in Figs. 1 and 2, viz., the continuous curve in Fig. 2 is more tilted than that in Fig. 1. This is due to the squeezing inherent in the initial state of the system (26) which is quantified by the parameters \( r_1 \) and \( \psi \).

**B. System of an anharmonic oscillator**

Here we take up the case where the system is modeled as an anharmonic oscillator with the Hamiltonian

\[
H_S = \hbar \omega \left( a^2 + \frac{1}{2} \right) + \frac{\hbar \lambda}{2} (a^4 + a^2 a'^2). \tag{30}
\]

This has been used, for example, in studies related to a non-absorbing Kerr medium interacting with a single mode of the quantized electromagnetic field [37,38]. In such a context \( \lambda \) is related to the third-order susceptibility of the Kerr medium [48]. The above Hamiltonian can be expressed (up to constant factors) in terms of the generators \( K_0, K_+, K_- \) of the SU(1,1) group. These generators have the following bosonic representation:

\[
K_0 = -\frac{1}{4}(a^2 + a'^2), \quad K_+ = \frac{1}{2} (a^2), \quad K_- = \frac{1}{2} (a^2). \tag{31}
\]

In terms of these generators, Eq. (30) can be expressed as

\[
H_S = 2\hbar \omega K_0 + 2\hbar \lambda K_+ K_- \tag{32}
\]

We make use of the unitary irreducible representations of the group SU(1,1) known as the positive discrete series \( D^+_k \), where \( k \) is the so-called Bargmann index [49], such that the eigenvalue of the Casimir operator of the group is \( k(k-1) \). This gives the value of \( k \) to be \( \frac{1}{4} \) or \( \frac{1}{2} \) [50,51]. The case of \( k=\frac{1}{2} \) marks the even sector of the representation with the vacuum state in this representation coinciding with the vacuum state of the harmonic oscillator, while the case of \( k=\frac{1}{4} \) marks the odd sector of the representation. Thus the even and the odd sectors of the representation together span the number states [52]. The basis for this representation obeys the following properties:

\[
K_0 |m,k\rangle = (m+k)|m,k\rangle, \quad K_+ |m,k\rangle = \sqrt{(m+1)(m+2)|m+1,k\rangle}, \quad K_- |m,k\rangle = \sqrt{(m+2)(m+1)|m-1,k\rangle}, \tag{33}
\]

where \( m=0,1,2,\ldots \). Using the above properties of the generators, the action of \( H_S \) (30) on the basis of this representation is found to be

\[
H_S |m,k\rangle = 2\hbar [\omega(m+k) + \lambda(m+2k-1)]|m,k\rangle = E_m |m,k\rangle. \tag{34}
\]

We use the above equation in Eq. (7) to obtain the reduced density matrix of the system \( S \) in the system basis \( |m,k\rangle \) as

\[
\rho_{nm,k}^{\rho}(t) = e^{-2\hbar(m-n)(\omega+\lambda(m+n+2k-1))\vartheta(t)} \times e^{4\hbar^2(m-n)(\omega+\lambda(m+n+2k-1))\vartheta(t)} |E_m| |E_m\rangle \langle E_m| \langle E_m| |E_m\rangle \langle E_m| \rho_{nm,k}^{\rho}(0). \tag{35}
\]
Now let us consider some physically interesting initial conditions for our anharmonic oscillator system \( S \).

1. System initially in a Kerr state

An initial Kerr state \( |\psi_K\rangle \) [37] can be obtained as a result of an interaction of the usual coherent state of the electromagnetic field with a nonlinear Kerr medium given in Eq. (30). This state is defined in terms of the number states as

\[
|\psi_K\rangle = \sum_n q_n |n\rangle ,
\]

where

\[
q_n = \frac{n!}{\sqrt{n}} e^{-|\alpha|^2/2} e^{-i\lambda n(n-1)} .
\]

Here \(|n\rangle\) represents the usual number state and \( \lambda = \frac{\beta}{2} \), where \( \beta \) is as in Eq. (30), \( L \) is the length of the medium, and \( v \) is the speed of light in the Kerr medium in which the interaction has taken place. Thus the initial system density matrix is

\[
p_{mk,\nu}^k(0) = \langle m, k | \psi_K\rangle \langle \psi_K | n, k \rangle
= q_{2n} \delta_{2n}^* \text{ for } k = \frac{1}{4}
= q_{2n+1} \delta_{2n+1}^* \text{ for } k = \frac{3}{4},
\]

because the state \(|m, k\rangle\) with \( k = \frac{1}{4} \) represents an even number state while the state \(|m, k\rangle\) for \( k = \frac{3}{4} \) represents an odd number state. The phase distribution is obtained as follows, by substituting Eq. (38) in Eq. (35) and then in Eq. (16), making use of the fact that for the positive discrete series representation of the group \( SU(1,1) \), the even and the odd sectors together span the number states:

\[
P(\theta) = \frac{1}{2\pi} \sum_{m,n=0}^{\infty} q_{2m} q_{2n}^* e^{2i(m-n)\theta} e^{-2i(n(m+n-1)\beta)} \times e^{4\beta^2(m-n)[(m+n+1)/2]}[m(2m+1)\alpha^2 + \alpha^2] \langle m | \psi_{SK} \rangle \langle \psi_{SK} | n \rangle
= q_{2m} q_{2n}^* e^{2i(m-n)\theta} e^{-2i(n(m+n-1)\beta)} \times e^{4\beta^2(m-n)[(m+n+1)/2]}[m(2m+1)\alpha^2 + \alpha^2] \langle m | \psi_{SK} \rangle \langle \psi_{SK} | n \rangle
= q_{2m+1} q_{2n+1}^* e^{2i(n(m+n-1)\beta)} e^{-2i(n(m+n-1)\beta)} \times e^{4\beta^2(m-n)[(m+n+1)/2]}[m(2m+1)\alpha^2 + \alpha^2] \langle m | \psi_{SK} \rangle \langle \psi_{SK} | n \rangle .
\]

Figures 3 and 4 represent the evolution of the quantum phase distribution \( P(\theta) \) given by Eq. (39), as a function of \( \theta \) for an anharmonic oscillator system (30) starting from an initial Kerr state (36). While Fig. 3 represents the evolution for a fixed evolution time but different environmental conditions, Fig. 4 represents different evolution times under the same environmental conditions. From Fig. 3 it is evident that increasing the temperature \( T \) causes a broadening of the phase distributions. Increased phase diffusion also results from an increase in environmental squeezing \( r \). Figure 4 clearly shows that with an increase in the evolution time \( r \), i.e., an increase in exposure to the environment, the quantum phase distribution shifts as well as diffuses. A similar conclusion was obtained by Agarwal et al. [35] for an analogous situation studied under unitary evolution.

2. System initially in a squeezed Kerr state

A squeezed Kerr state [37] is defined in terms of the number states as

\[
|\psi_{SK}\rangle = \sum_m s_m |m\rangle .
\]

Thus the initial system density matrix in the system basis \(|m, k\rangle\) (34) is
The dotted curve is for an evolution time \( T=0 \) and \( r=2 \). The continuous curve represents unitary evolution (\( \gamma_0=0 \)).

Here \( F^2 \) is the Gauss hypergeometric function [54]. We make use of even \( p \) in Eqs. (42) and (44), and odd \( p \) in Eqs. (43) and (45), because as has been pointed out in [53], \( G_{mm} \) is nonzero only for \( m,n \) either both even or both odd. Since \( m \) is even in Eq. (42), it follows that \( p \) too should be even, and similarly for Eq. (43) where \( m \) is odd. For convenience, it is sometimes assumed that \( \phi \) is zero and \( z=r_1 \) is real. Using Eqs. (42)-(45) in Eq. (41), substituting it in Eq. (35), and then in Eq. (16), we obtain the phase distribution function as

\[
G_{2m+12p+1} = \frac{(-1)^p m!}{p! m!} \frac{(2p+1)!(2m+1)!}{\cosh^3(r_1)} \frac{1}{\sinh(r_1)^3} \cdot \exp[i(m-p)\phi] \times \left( \frac{\tanh(r_1)}{2} \right)^{(m+p)} F^2 \left[ -\frac{p-m}{2}, -\frac{1}{2} \right].
\]

(45)

Here \( F^2 \) is the Gauss hypergeometric function [54]. We make use of even \( p \) in Eqs. (42) and (44), and odd \( p \) in Eqs. (43) and (45), because as has been pointed out in [53], \( G_{mm} \) is nonzero only for \( m,n \) either both even or both odd. Since \( m \) is even in Eq. (42), it follows that \( p \) too should be even, and similarly for Eq. (43) where \( m \) is odd. For convenience, it is sometimes assumed that \( \phi \) is zero and \( z=r_1 \) is real. Using Eqs. (42)-(45) in Eq. (41), substituting it in Eq. (35), and then in Eq. (16), we obtain the phase distribution function as

\[
G_{2m+12p+1} = \frac{(-1)^p m!}{p! m!} \frac{(2p+1)!(2m+1)!}{\cosh^3(r_1)} \frac{1}{\sinh(r_1)^3} \cdot \exp[i(m-p)\phi] \times \left( \frac{\tanh(r_1)}{2} \right)^{(m+p)} F^2 \left[ -\frac{p-m}{2}, -\frac{1}{2} \right].
\]

(45)

Here \( F^2 \) is the Gauss hypergeometric function [54]. We make use of even \( p \) in Eqs. (42) and (44), and odd \( p \) in Eqs. (43) and (45), because as has been pointed out in [53], \( G_{mm} \) is nonzero only for \( m,n \) either both even or both odd. Since \( m \) is even in Eq. (42), it follows that \( p \) too should be even, and similarly for Eq. (43) where \( m \) is odd. For convenience, it is sometimes assumed that \( \phi \) is zero and \( z=r_1 \) is real. Using Eqs. (42)-(45) in Eq. (41), substituting it in Eq. (35), and then in Eq. (16), we obtain the phase distribution function as

\[
P(\theta) = \frac{1}{2\pi} \sum_{m,n=0}^{\infty} s_{2m+12n+1} e^{2i(m-n)\theta} e^{-2(m-n)\left[\omega + \lambda(m+n-1/2)\right]} \times e^{4\lambda^2(m-n)^2 \left[\omega + \lambda(m+n-1/2)\right]} \times e^{4\lambda^2\left[\omega + \lambda(m+n-1/2)\right]} \times e^{4\lambda^2\left[\omega + \lambda(m+n-1/2)\right]}.
\]

(46)

Here \( s_{2m+12n+1} \) is as in Eq. (42) and \( s_{2m+1} \) is as in Eq. (43).

Figure 5 depicts the evolution of the quantum phase distribution \( P(\theta) \) given by Eq. (46), as a function of \( \theta \) for an anharmonic oscillator system (30) starting from an initial squeezed Kerr state (40). The environmental effects are clearly depicted in that an increase in temperature \( T \) and squeezing parameter \( r \) results in the broadening of the phase distribution indicating increased phase diffusion. In the same figure, a drastic influence of the environment on the unitary behavior can be seen from the sharp fall in the amplitude of the phase distribution with the inclusion of environmental effects. A comparison between the unitary evolutions (continuous curves) of Figs. 3 and 5 highlights the difference in the initial conditions of the system depicted in these curves. The peak amplitude of the unitary evolution (continuous curve) is greater in case of a system initially in a squeezed Kerr state (Fig. 5) than that in a Kerr state (Fig. 3). This is indicative of the additional squeezing in the initial state for Fig. 5. The corresponding narrowing of the peaks in Fig. 5 is due to the fact that the phase distributions are normalized. Note that the multiple peaks are a common feature of the quantum phase distributions of the anharmonic oscillator system (30) as opposed to the single peaks of the harmonic oscillator system (18).
ANERJEE, GHOSH, AND GHOSH

FIG. 6. Quantum phase distribution $P(\phi)$ given by Eq. (62), for a two-level atom initially in an atomic coherent state, as a function of $\phi$ (in radians), for different environmental conditions and evolution times. The parameters have been taken as $\alpha = \beta = \pi/4$ [Eq. (58)], and $\gamma_0 = 0.025$. The continuous curve and the dotted curve are for the bath squeezing parameter $r = 0$ and 2, respectively, at a temperature $T = 0$ and an evolution time $\tau = 0.1$. The small-dashed and the large-dashed curves correspond to evolution times $\tau = 0.1$ and 3.02, respectively, at $T$ (in units with $\hbar = k_B = 1) = 300$ and $r = 2$.

IV. QUANTUM PHASE DISTRIBUTION OF A TWO-LEVEL ATOMIC SYSTEM

In this section we discuss the case where our system S is a two-level atom with a representation of the group SU(2). The system Hamiltonian, to be substituted in Eq. (1), is

$$H_S = \hbar \omega \sigma_z,$$

(47)

where $\sigma_z$ is the usual Pauli matrix (as has been used, for example, in the quantum computation models in [39–41]). The Wigner-Dicke states [43,44,55] $\{j, m\}$, which are the simultaneous eigenstates of the angular momentum operators $J^2$ and $J_z$, serve as the basis states for $H_S$ and we have

$$H_S|j, m\rangle = \hbar \omega m |j, m\rangle = E_{j, m}|j, m\rangle.$$

(48)

Here $-j \leq m \leq j$. Using this basis and the above equation in Eq. (7) we obtain the reduced density matrix of the system as

$$\rho^{(i)}(t) = e^{-i\omega (m-n)\tau} e^{i\omega^{(m-n)^2}\tau} \rho^{(0)}(0).$$

(49)

Following Agarwal and Singh [42] we introduce the phase distribution $P(\phi)$, $\phi$ being related to the phase of the dipole moment of the system, as

$$P(\phi) = \frac{2j+1}{4\pi} \int_0^\pi d\theta \sin \theta Q(\theta, \phi).$$

(50)

where $P(\phi) > 0$ and is normalized to unity, i.e., $\int_0^{2\pi} d\phi P(\phi) = 1$. Here $Q(\theta, \phi)$ is defined as

$$Q(\theta, \phi) = \langle \theta, \phi | \rho^{(i)} | \theta, \phi \rangle,$$

(51)

where $|\theta, \phi\rangle$ are the atomic coherent states [56,57] given by an expansion over the Wigner-Dicke states [44] as

$$|\theta, \phi\rangle = \sum_{m=-j}^j \sqrt{j+m} e^{-i(m+n+1)\phi} e^{i\omega (m-n)^2/2\tau} |j, m\rangle.$$

yielding the following matrix element in the $|j, m\rangle$ basis:

$$\langle j, n | \rho^{(i)} | j, m \rangle = e^{-i\omega (m-n)\tau} e^{i\omega^{(m-n)^2}\tau} e^{-i(m+n+1)\phi} e^{i\omega (m-n)^2\tau/2} \times \langle j, n | \alpha, \beta \rangle \langle \alpha, \beta | j, m \rangle.$$

(52)

Using Eq. (51) in Eq. (50), with insertions of partitions of unity in terms of the Wigner-Dicke states, we can write the phase distribution function as

$$P(\phi) = \frac{2j+1}{4\pi} \int_0^\pi d\theta \sin \theta \sum_{n=-j}^j \langle \theta, \phi | j, n \rangle |\rho^{(i)}(j, n)|.$$

(53)

We make use of Eq. (49) and

$$\langle j, n | \rho^{(i)} | j, m \rangle = \left( \frac{2j}{j+m} \right)^{1/2} \sin(\theta/2)^{j+m} \cos(\theta/2)^{j-m} e^{-i(j+m)\phi},$$

(54)

and its conjugate in Eq. (53) to obtain the required phase distribution for specific initial conditions of the system $S$. Let us now consider some physically interesting initial conditions for the two-level system $S$.

A. System initially in a Wigner-Dicke state

A Wigner-Dicke state is the atomic analogue of the Fock state [44]. The initial density matrix of the system $S$ in this case is

$$\rho^{(0)}(0) = |j, m\rangle \langle j, m|.$$

(55)

which gives

$$\langle j, n | \rho^{(i)} | j, m \rangle = \delta_{j, m} \delta_{n, m}.$$

(56)

Using this, the phase distribution becomes

$$P(\phi) = \frac{2j+1}{2\pi} \left( \frac{2j}{j+m} \right) B[j + m + 1, j - m + 1].$$

(57)

Here $B$ stands for the beta function. It is evident from Eq. (57) that the phase distribution for the atomic system starting in a Wigner-Dicke state is uniform and is independent of any bath dynamics. Here, since we have only one two-level system in Eq. (47), $j = \frac{1}{2}$ and $P(\phi)$ can be seen to go over to $\frac{1}{2\pi}$, i.e., a uniform distribution.

B. System initially in an atomic coherent state

An atomic coherent state is the atomic analogue of the Glauber coherent state [44]. The initial density matrix of the system $S$ in this case is

$$\rho^{(0)} = |\alpha, \beta\rangle \langle \alpha, \beta|,$$

(58)

yielding the following matrix element in the $|j, m\rangle$ basis:

$$\langle j, n | \rho^{(i)} | j, m \rangle = e^{-i\omega (m-n)\tau} e^{i\omega^{(m-n)^2}\tau} e^{-i(m+n+1)\phi} e^{i\omega (m-n)^2\tau/2} \times \langle j, n | \alpha, \beta \rangle \langle \alpha, \beta | j, m \rangle.$$

(59)
Using Eqs. (59) and (54) in Eq. (53) we obtain the phase distribution as

\[
P(\phi) = \frac{2j+1}{4\pi} \int_0^\pi d\theta \sin \theta \sum_{n,m=-j}^{j} \left( \frac{2j}{j+n} \right) \left( \frac{2j}{j+m} \right) [\sin(\theta/2)]^{2|j+n+m|} \times [\cos(\theta/2)]^{2|n-m|} \sin[(\alpha/2)|n-m|] \sin[(\alpha/2)|n+m|] \sin[(\alpha/2)(n-m)] e^{i(\alpha/2)(n-m)\phi} e^{-(\alpha/2)(n-m)\phi}.
\]

In the above equation, the integral can be carried out to yield

\[
P(\phi) = \frac{2j+1}{2\pi} \sum_{n,m=-j}^{j} \left( \frac{2j}{j+n} \right) \left( \frac{2j}{j+m} \right) \frac{\Gamma(j+1/2(n+m)+1)}{\Gamma(j+1/2(n+m)+1)} \frac{\Gamma(j-1/2(n+m)+1)}{\Gamma(2j+2)} e^{-(n-m)^2} \sin[(\alpha/2)|n-m|] \sin[(\alpha/2)|n+m|] \sin[(\alpha/2)(n-m)] e^{-(\alpha/2)(n-m)\phi} e^{-(\alpha/2)(n-m)\phi}.
\]

Here \( \Gamma \) is the standard gamma function. Since \( H_S \) given by Eq. (47) represents a single two-level atom, \( j = j/2 \). Eq. (61) is thus considerably simplified and we obtain the phase distribution as

\[
P(\phi) = \frac{1}{2\pi} \left[ 1 + \frac{\pi}{4} \sin \alpha \cos(\beta + \omega t - \phi) e^{-(\alpha/2)(n-m)^2} \right].
\]

It can be easily checked that this \( P(\phi) \) is normalized to unity. As can be seen from Eq. (62), only \( \gamma(t) \) plays a role in carrying the effect of the environment on the phase distribution. For a generic QND open quantum system described by Eq. (1), it can be shown that \( \gamma(t) \) is the decoherence causing term [36]. Thus Eq. (62) is a simple and neat formula clearly illustrating the effect of the environment on phase diffusion. By making use of \( \gamma(t) \) from Eqs. (13) and (14) for \( T = 0 \) and for high \( T \), respectively, we find that the second term on the right-hand side of Eq. (62) has a power-law decay at zero \( T \) and an exponential decay at high \( T \), and eventually the phase distribution tends to the uniform limit of \( \frac{1}{2\pi} \). Thus the effect of the environment stays for a longer time at zero \( T \) as compared to that at high \( T \).

Figure 6 depicts the evolution of the quantum phase distribution \( P(\phi) \) given by Eq. (62), as a function of \( \phi \) (in radians) for different environmental conditions. It is clearly seen that increasing the temperature \( T \), the bath squeezing parameter \( r \), and the environment exposure time \( t \) cause a broadening of the phase distribution curve, indicating an increase of phase diffusion. The broadening of the curves preserves the normalization of the phase distribution.

C. System initially in an atomic squeezed state

An atomic squeezed state [45,56–58] is expressed in terms of the Wigner-Dicke states as

\[
|\zeta, p\rangle = A_p \exp(\Theta J_2) \exp\left(-i\frac{\pi}{2} J_y\right) |j,p\rangle,
\]

where

\[
e^{2\Theta} = \tanh(2|\zeta|),
\]

with \( \zeta \) indicating the initial squeezing of the system. The initial density matrix of the system \( S \) in this case is

\[
\rho(0) = |\zeta, p\rangle \langle \zeta, p|.
\]

Using Eq. (53) along with the expressions

\[
\langle j, n | \rho(t) | j, m \rangle = e^{-(\alpha/2)(j^2-n^2)} \phi(t) e^{-(\alpha/2)(n-m)^2} \gamma(t)
\]

and

\[
\langle j, n | \zeta, p \rangle = A_p e^{\Theta d_{np}(\frac{\pi}{2})},
\]

[56], where \( d_{np}(\frac{\pi}{2}) \) is the standard Wigner symbol for the rotation operator [59] as follows:

\[
d_{np}(\frac{\pi}{2}) = \langle j, n | e^{-i(\Theta/2)J_y} | j, p \rangle,
\]

and

\[
|A_p|^2 = \sum_r (\frac{1}{r!} (-1)^r (2j - r)! \cos(\Theta)^{2r})^{-1}
\]

we obtain the phase distribution function as

\[
P(\phi) = \frac{2j+1}{4\pi} |A_p|^2 \int_0^\pi d\theta \sin \theta \sum_{n,m=-j}^{j} \left( \frac{2j}{j+n} \right) \left( \frac{2j}{j+m} \right) \frac{1}{\Gamma(j+1/2(n+m)+1)} \frac{1}{\Gamma(j+1/2(n+m)+1)} \times [\sin(\theta/2)]^{2|n-m|} [\cos(\theta/2)]^{2|n-m|} e^{i(\alpha/2)(n-m)\phi} e^{-(\alpha/2)(n-m)\phi} e^{-(\alpha/2)(n-m)\phi} d_{np}^2 \frac{\pi}{2} d_{np}^2 \frac{\pi}{2}.
\]

In Eq. (70) the integral can be carried out to yield

\[
\frac{1}{\sqrt{2\pi}}
\]
As discussed in Sec. IV B above, for a single two-level system $j=\frac{1}{2}$. We take up two cases for the two values of $p$ appearing in Eq. (63): $p=-\frac{1}{2}$ called the south pole of the phase space of the two-level system, and $p=\frac{1}{2}$ called the north pole of the phase space [45].

(a) South pole $(p=-\frac{1}{2})$. The phase distribution in Eq. (71) is considerably simplified to give

$$P(\phi) = \frac{1}{2\pi} \left[ 1 - \frac{\pi}{4 \cos \Theta} \cos(\phi - \omega t) e^{-(\omega t)^2/\gamma(t)} \right] .$$ (72)

(b) North pole $(p=\frac{1}{2})$. Equation (71) is simplified to give

$$P(\phi) = \frac{1}{2\pi} \left[ 1 + \frac{\pi}{4 \cos \Theta} \cos(\phi - \omega t) e^{-(\omega t)^2/\gamma(t)} \right] .$$ (73)

$A_p$ is defined by Eqs. (63) and (67) and is usually fixed by normalization as in the above equations, where $|A_p|^2 = (\cos \Theta)^{-1}$ which is equal to 1 for $\Theta=0$ [56], implying an infinite initial squeezing $\xi$ of the system (64). The expression in Eq. (72) for the south pole in the phase space and that in Eq. (73) for the north pole in the phase space differ from each other by a sign in the second part of the expressions. The contrast between them can be seen clearly from Figs. 7 and 8. As seen from the figures, with the increase in temperature $T$ or the exposure time to the environment $t$, the phase distribution curves flatten out indicating increased phase diffusion. These curves bring out another notable feature, viz., with the increase in bath exposure time $t$ or temperature $T$, the effect of squeezing, indicated by the parameter $r$, is washed out. This behavior is analogous to the effect of squeezing in oscillator systems, where with the increase in bath exposure time $t$ and temperature $T$, the nonstationary effects introduced by the squeezed bath are washed out [60].

Equations (72) and (73) are easily seen to be normalized to unity. As in Sec. IV B above, the effect of the environment shows up in the above equations only in the function $\gamma(t)$, responsible for decoherence. As was the case in the previous Sec. IV B, from the forms of the function $\gamma(t)$, for an ohmic bath, given by Eqs. (13) and (14) for $T=0$ and for high $T$, respectively, we find that the second term on the right-hand side of Eqs. (72) and (73) has a power-law decay at zero $T$ and an exponential decay at high $T$, and eventually the phase distribution tends to the uniform limit of $\frac{1}{2\pi}$ seen in the case in Sec. IV A. Thus the effect of the environment stays for a longer time at zero $T$ as compared to high $T$, and eventually the distribution tends to the same uniform value irrespective of the initial state being a coherent or a squeezed state. As pointed out in [42,45,57], the state $|\xi,p\rangle$ in Eq. (63) has an inherent squeezing which is represented by $\xi$ in Eq. (64) and the environmental squeezing $r$ is encapsulated in the function $\gamma(t)$ given by Eq. (10). Thus the results (72) and (73) bring out the relative importance of the different squeezing sources and hence are applicable in the context of the experiment of

![FIG. 7. Quantum phase distribution $P(\phi)$ given by Eq. (72), at the south pole of the phase space for a two-level atom initially in an atomic squeezed state, as a function of $\phi$ (in radians), for different environmental conditions. The system squeezing parameter (64) $\Theta$ is taken as $-0.5494$, the bath squeezing parameter $r=1$, and $\gamma_0=0.025$. The continuous curve corresponds to a temperature $T=0$ and an evolution time $t=0.1$, while the small-dashed and large-dashed curves correspond to evolution times $t=0.1$ and 0.05, respectively, at $T$ (in units with $\hbar=\gamma_0=1$) $=300$.](image1)

Kuzmich et al. [23] concerning the role of the environment on the atomic quantum nondemolition measurements and squeezing.

V. CONCLUSIONS

In this paper we have analyzed the quantum phase distribution of a number of physically interesting systems interacting with their environment via a QND type of coupling. We have taken our system to be either an oscillator (harmonic or anharmonic) or a two-level atom (or equivalently, a spin-1/2 system), and modeled the environment as a bath of harmonic oscillators, initially in a general squeezed thermal state, from which the common thermal bath results may be easily extracted by setting the squeezing parameters to zero. We have explicitly evaluated the phase distribution and worked out the effects of different environmental parameters on the dynamics of the system starting with various initial states.

In particular, for a harmonic oscillator system in QND interaction with its environment (Sec. III A), we have considered two different initial conditions of the system, starting (1) in a coherent state and (2) in a squeezed coherent state. The phase distribution corresponding to the unitary evolution in the second case is more tilted than that in the first case, which is a signature of the squeezing inherent in the initial state of the system. We have next taken an anharmonic oscillator (Sec. III B), which could arise, for example, from the interaction of a single mode of the quantized electromagnetic field with a Kerr medium, and constructed its phase distribution, again for different initial conditions: (1) the system starting in a Kerr state, and (2) the system starting in a squeezed Kerr state. With an increase in the evolution time \( t \), indicating an increase in exposure to the environment, the quantum phase distribution in the first case shifts as well as diffuses.

We have then studied the phase distribution for a discrete two-level atom (Sec. IV), for different initial conditions of the system, starting (1) in a Wigner-Dicke state, which is the atomic analog of the standard Fock state, (2) in an atomic coherent state, which is the atomic analogue of the Glauber coherent state, and (3) in an atomic squeezed state. In the first test case, the phase distribution is uniform and is independent of any bath dynamics. In the other two cases, it is seen that the effect of the environment stays for a longer time at zero temperature than that at high temperature, and eventually the distribution tends to the uniform value of the first case, irrespective of the initial state of the system.

In all the cases considered, a broadening of the phase distribution curve, indicating an increase in phase diffusion, results with an increase in the bath temperature \( T \) or bath squeezing parameter \( r \) or evolution time \( t \). The broadening of the curves, of course, preserves the normalization of the phase distribution. Even though each system considered is an "open" system, we could make use of the underlying group symmetries of the system Hamiltonians, because of the QND nature of the system-environment coupling. Our quantitative results are of potential use in the analysis of a broad class of relevant experimental situations dealing with quantum nondemolition measurements and squeezing.
